

Effect of TGF- β 1 on Water Retention Properties of Healthy and Osteoarthritic Chondrocytes

Tehmeena Israr Raja, Seyed Ali Khaghani, Muhammad Sohail Zafar, Zohaib Khurshid, Masoud Mozafari, Mansour Youseffi, Farshid Sefat

Abstract

Articular cartilage, a connective tissue, contains chondrocytes and glycosaminoglycans (GAGs) which aid in water retention, providing the tissue with its magnificent ability to prevent friction, withstand loads and absorb compressive shocks however, cartilage, does not have the ability to regenerate and repair. Osteoarthritis (OA) is a progressive degenerative disease, which includes reduction of cartilage thickness between two bones in a joint, causing painful bone-to-bone contact. OA affects over 8 million people in the UK alone. , and as the primary causes are unknown, available treatments including surgical and non-surgical techniques which only reduce the symptoms created by the disorder instead of providing a cure. This project focused on utilizing TGF- β 1, a cytokine found in elevated amounts in healthy cartilage when compared to degraded cartilage, in order to observe the effects of the growth factor on both healthy and osteoarthritic chondrocytes. The healthy and the osteoarthritic chondrocytes were cultured in two different media (DMEM with and without TGF- β 1) before utilizing the SpectraMax M2/M2e plate reader to observe and analyze the effect of TGF- β 1 on water retention properties of cells. This has been achieved by quantifying the GAG content using DMMB dye. Results showed that although TGF- β 1 did displayed an increase in glycosaminoglycan synthesis, the statistical increase was not vast enough for the alternative hypothesis to be accepted; further experimentation with TGF- β 1, alongside other cytokines within the growth factor family is needed to perceive the true influence of the growth factor on uncured degenerative diseases. It was concluded that both the healthy and osteoarthritic cells treated with TGF- β 1 absorbed considerably more DMMB in comparison to the cells, suggesting that TGF- β 1 indeed works to aid in water retention. TGF- β 1 is a key factor to be exploited when constructing treatments for osteoarthritis.

Keywords: TGF- β 1; cytokines; water retention; articular cartilage; chondrocytes; osteoarthritis; immunocytochemistry; DMMB.

1. Introduction

Osteoarthritis is a progressive degenerative disease, which includes reduction of cartilage thickness between two bones in a joint, causing painful bone-to-bone contact. Cartilage is retained within the synovial capsule present at the sight of each joint, reducing friction and absorbing shock; the synovium which surrounds each capsule when one is suffering from OA swells, and as the synovium becomes inflamed, it produces a diseased synovial fluid which further affects the joint. This fluid remains in contact with the ligaments, causing them to contract leading to a reduction in thickness;

the muscle attached to the ligament aiding in the affected joints movement is weakened as a result, and said muscle becomes stiff, reducing range of motion. In osteoarthritis, proteoglycans from articular cartilage are said to be lost [1]. There are many factors which promote arthritis but one of the main hallmarks of OA occurring is a reduction in proteoglycan presence. It is thought to be lost in the damaged matrix and due to this, the hydrophilic nature of the basket like structure is reduced, decreasing water retention [2].

Articular cartilage is a highly specialised form of tissue. Being avascular, it can only gain its nutrients through diffusion. The extracellular matrix consists of mainly two macromolecules including the proteoglycan aggrecan and also collagen (mostly type II). Chondrocytes, the main resident cell in articular cartilage coordinate the synthesis, maintenance and degradation of proteins existent in the extracellular matrix. In cartilage that is considered healthy, the

chondrocytes are in a state of dormancy due to the balance of synthetic and catabolic actions whereas when a cartilage has been partially degraded or when trauma has occurred to the joint, water retention properties are lost and an up regulation of catabolic pathways occur [2]. Damage to the cartilage that occurs in osteoarthritic situations may be a result of a misbalance between factors, with catabolic overpowering anabolic reactions.

Despite many attempts, a method of repairing cartilage that is damaged when osteoarthritis occurred had not been finalised. An existing approach considers fluctuating metabolic imbalances back to the original state by causing a stimulation acting upon the anabolic reactions. TGF- β 1 is an anabolic factor which is directly linked to maintaining the cartilage, working by stimulating ECM production, downgrades degrading cytokines [3] and therefore, is an

appropriate option to be observed; TGF- β 1 signalling serves as a potential key target for therapeutic intervention for the treatment of OA disease [4-6].

3. Materials and Methods

~~3.1. Cell isolation and culture, healthy and Osteoarthritic Chondrocytes~~
This research work focuses on considering to what extent TGF- β 1 can affect the water retention properties of both healthy and osteoarthritic chondrocytes taken from the knee joint of a Swiss white mouse. By manipulating the media in which the cells are cultured (using the growth factor as a variable) and through the staining of proteoglycans, quantification of GAGS can be achieved/ and absorbance of stain can be measured. If the TGF- β 1 demonstrates significant differences in terms of increasing water retention (increased absorbance in the samples containing the growth factor in comparison to the samples cultured in ordinary media), it can be confirmed that TGF- β 1 is a focal point for curing the degenerative disease [7].

2. Aims and Objectives

The aim of this research work was to investigate the effect of TGF- β 1 on water retention properties of glycosaminoglycans on both healthy and osteoarthritic chondrocytes.

3. Materials and Methods

3.1. Cell isolation and culture; healthy and osteoarthritic chondrocytes

Chondrocyte were isolated and purified from the knee joint of a Swiss white Mouse. Reagents were used included high glucose DMEM (4500mg/l glucose) inclusive of serum, Hanks balanced salt solution (HBSS), trypsin and collagenase type-IA 10% v/v [8]. The DMEM was induced with 20% v/v fetal bovine serum (FBS), 2.5 U/ml L-glutamine, 100 U/ml penicillin, 0.1mg/ml streptomycin and 1 µg Amphotericin B [9]. Cartilage samples were carefully isolated from 7 days old euthanized Swiss white mice at the knee joint as described previously [10]. Briefly, the tissue

was washed with HBSS, eliminating the chances of having tissue other than cartilaginous (such as adipose or blood cells) present in the culture sample. The cartilage samples were soaked in 4ml of trypsin at 37 degrees for 15 minutes and stirred using magnetic stirrer. The supernatant was transferred into a sterilised 15ml centrifuge tube containing 6ml DMEM and 10%FBS in order to stop activation of trypsin. After three repeats, these suspensions were combined and centrifuged for 5 minutes at 2000rpm. The excess media was discarded before the pellet was re-suspended in 1ml collagenase, stirred for 90 minutes at 37 degrees. The suspension was combined with 4ml of DMEM in order to

3. Materials and Methods

3.1. Cell isolation and culture; healthy and osteoarthritic chondrocytes

prevent further action of collagenase, and centrifuged for 5 minutes at 2000rpm before the excess media was discarded. The pellet was further re-suspended in 6ml of DMEM induced with 0.1mg/ml hyaluronic acid before being placed in a 25cm²-culture flask and incubated at 37 degrees for 24 hours [8].

3.1.1. Primary cell culture

A sample of the isolated chondrocytes were taken and chemically induced in order to replicate osteoarthritic conditions; the two groups included healthy and osteoarthritic chondrocytes. Both variations of cells were cultured and reagents included; hanks balanced salt solution (HBSS), trypsin, and High glucose DMEM (4500mg/l) induced with 10% fetal bovine serum (FBS), 2.5 U/ml L-glutamine, 100 U/ml penicillin, 0.1mg/ml streptomycin and 1µg Amphotericin B [8, 10]. The isolated chondrocyte cell culture flask was taken and the media was removed, leaving the monolayer of chondrocytes. The chondrocyte monolayer of cells was washed with 3ml of HBSS after the media

3. Materials and Methods

3.1. Cell isolation and culture; healthy and osteoarthritic chondrocytes

was removed in order to deactivate the serum present in the DMEM. After three repeats, 6ml of trypsin was added to the culture flask and incubated at 37 degrees for 2 minutes. After 90% of cells were dislodged, 12ml of the DMEM was added to the cell suspension. The cell suspension was then split into two sterilised 9ml labelled centrifuge tubes, and centrifuged at 1700rpm for 5 minutes. The supernatant of tube 1 was removed, and the pellet re-suspended in 6ml DMEM, transferred into a 25cm² cell culture flask labelled HCH (for healthy chondrocytes) and incubated at 37 degrees for 24 hours. The supernatant from tube 2 was removed, the pellet re-suspended in 6ml DMEM containing

chemicals that induce osteoarthritic conditions, transferred into a second (labelled OACH) 25cm²-culture flask and also incubated at 37 degrees for 24 hours. After 24 hours, samples of healthy chondrocytes and osteoarthritic chondrocytes had been obtained; both cell types underwent a sub culture; media from both culture flasks (HCH and OACH) was removed, the monolayers rinsed with 1ml HBSS twice, 2ml trypsin added to both flasks before incubation at 37 degrees for 2 minutes, furthermore combined with 6ml of DMEM. The cell suspensions were centrifuged for 5 minutes at 1700rpm before the pellets were re-suspended in High glucose DMEM (4500mg/l) induced with 10% fetal

3. Materials and Methods

bovine serum (FBS), 2.5 U/ml L-glutamine, 100 U/ml penicillin, 0.1mg/ml streptomycin and 1µg Amphotericin B. 6ml of healthy chondrocyte suspension were again transferred into a sterilised 25cm² labelled culture flask (HCH + 48hr) using a pipette, and likewise 6ml of the osteoarthritic chondrocyte suspension was transferred into a 25cm² labelled culture flask (OACH + 48hr); both samples incubated for a further 24 hours at 37 degrees.

3.1.2. Secondary culture and TGF-β1 treatment

Healthy and osteoarthritic chondrocytes were further cultured with two different types of media. Media type I included high glucose DMEM (4500mg/l) supplemented with 10% fetal bovine serum (FBS), 2.5 U/ml L-glutamine, 100 U/ml penicillin, 0.1mg/ml streptomycin and 1 µg Amphotericin B. Media type II included high glucose DMEM (4500mg/l) supplemented with 10% fetal bovine serum (FBS), 2.5 U/ml L-glutamine, 100 U/ml penicillin, 0.1mg/ml streptomycin

3. Materials and Methods

and 1µg Anaphotycin B and 100ng/20ml of TGF-β1. Media of both culture flasks (HCH + 48hr and OACH + 48hr) was removed; the monolayers rinsed with 1ml HBSS twice, 2ml trypsin added to both flasks before incubation at 37°C for 2 minutes and furthermore combined with 6ml of DMEM. The cell suspensions were centrifuged for 5 minutes at 1700rpm before the pellets were re-suspended in media type I. A vile containing 20µm of TGF-β1 (100ng/20ml) was centrifuged before extraction, combined with 5ml of DMEM (media type I) in order to create media type II (20ng/ml). 300µl of healthy cell suspension was placed into a labelled petri dish with an additional 300µl of media type I. 300µl of healthy cell suspension was placed into a second labelled petri dish (healthy chondrocyte + TGF-β1) with an additional 300µl of media type II. 300µl of osteoarthritic cell suspension was placed into a third labelled petri dish (osteoarthritic chondrocyte control) with an additional 300µl of media type I. 300µl of osteoarthritic

cell suspension was placed into a fourth labelled petri dish (osteoarthritic chondrocyte + TGF- β 1) with an additional 300 μ l of media type II.

3.2. Analysis of glycosaminoglycan content using the SpectraMax M2/M2^e plate reader

A plate reader (SpectraMax M2/M2^e, USA) was used to analyse the 4 culture samples described previously for GAG concentration with absorbance read at 525nm. The plate reader was calibrated to allow 5-second shake before the first read and left to analyse the well plate. Reagents included DMMB dye and were prepared from 0.00064g of pure DMMB, induced in 400ml deionised water, 1.216g glycine, 0.64g sodium chloride and 38ml of 0.1M acetic acid [11].

Cell suspension was taken from the four petri dishes and centrifuged separately at 800rpm for 5 minutes. A sterile 96 well plate was used for GAG analysis using SpectraMax M2/M2^e plate reader. Table 3 show different concentration of DMMB for both osteoarthritic and healthy cells.

3.1. Cell isolation and culture; healthy and osteoarthritic chondrocytes

Table 1. Different concentration of reagents and DMMB for analysis of GAGs.

Osteoarthritis Cells	
90µl of osteoarthritic cell supernatant induced with TGF-β1	190µl DMMB
60µl of degraded cell supernatant induced with TGF-β1	220µl DMMB
30µl of degraded cell supernatant induced with TGF-β1	250µl DMMB

90µl of OA cell control supernatant	190µl DMMB
60µl of OA cell control supernatant	220µl DMMB
30µl of OA cell control	250µl DMMB
Healthy Cells	
90µl of healthy cell supernatant control	190µl DMMB
60µl of healthy cell supernatant control	220µl DMMB
30µl healthy cell supernatant control	250µl DMMB
90µl of healthy cell supernatant induced with TGF-β1	190µl DMMB
60µl of healthy cell supernatant induced with TGF-β1	220µl DMMB

30µl healthy cell supernatant induced with TGF-β1	250µl DMMB

3. Materials and Methods

3.B. Statistical analysis using Minitab™ and 2 sample T test for significance

Minitab, an analysis software, was utilised in order to easily assimilate statistical data. 2-sample T test was used for this research work to quantify the difference present in glycosaminoglycan synthesis.

4. Result and Discussion

4.1. Cell isolation and culture; healthy and osteoarthritic chondrocytes

Table 2 – Cell Isolation

Shows the original primary cells floating after isolation, dispersed in fresh media before culturing to double. These cells were considered healthy, and demonstrated a rounded shape as chondrocytes show in vitro. The cells were then incubated for attachment and division to occur.

Figure 1 – Isolated healthy chondrocytes, (Scale bar = 100).

Primary cell culture

Table 3 – Primary culture

Secondary culture

Table 4 – Secondary culture; Healthy chondrocytes

	Healthy chondrocyte, control	Healthy chondrocytes treated with TGF- β 1
0 hours after culture	 <p>Figure 5 - Re-suspended floating healthy chondrocytes (control) immediately after being placed into the petri dish, (Scale bar = 100).</p>	 <p>Figure 6 - Re-suspended healthy chondrocytes treated with TGF-β1 immediately after being placed into the petri dish, (Scale bar = 100).</p>
24 hours after culture	 <p>Figure 7 - Re-suspended healthy chondrocytes (control without TGF-β1) 24 hours after being placed into the petri dish, (Scale bar = 100).</p>	 <p>Figure 8 - Re-suspended healthy chondrocytes treated with TGF-β1, 24 hours after being placed into the petri dish, (Scale bar = 100).</p>

During cell isolation and culture a change in morphology was seen between healthy and osteoarthritic cells after the first subculture (See Table 2 and 3, Figures 1-4). The culture flask and petri dishes containing the osteoarthritic chondrocyte suspension after 24 hours contained media did not match the colour of the media in which the healthy chondrocytes are contained. The Culture of primary cells in the first 24 hours was successful, allowing acceptable doubling for a good quantity of cells to work with. Before the use of trypsin after 24 hours, fibroblast like attachments were observed; the orientation of the cells were randomised, which is a well-known sign for healthy chondrocytes in vitro [8].

The secondary culture of both healthy and degraded cells was also a success, providing us with microscopic images, which portrayed images of rounded morphology in healthy cartilage cells in vitro, alongside a visual aid of the more fibroblastic differentiated morphology of osteoarthritic cells in vitro (See Table 4, Figures 5-8). The difference in quantity could also be clearly seen, showing that in the same amount of time, healthy cells created a larger amount of cells compared to degraded cells.

The final forms of culture which has been treated with and without TGF- β 1 were also successful, portraying that the samples induced with TGF- β 1 (both healthy and osteoarthritic) contained a larger amount of Glycosaminoglycans, confirmed via quantification of cells after 24 hours of culture (See Table 5, Figures 9-12). Also the differentiation of

morphology was observed after growth factor induction, from the rounded chondrocyte to more that of a fibroblastic change. The samples, which were cultured with standard DMEM, contained less viable cells, and the healthy cells did not have a dramatic change in terms of morphology.

Table 5 - Secondary culture; Osteoarthritic chondrocytes		
	Osteoarthritic chondrocyte (control)	Osteoarthritic chondrocytes treated with TGF- β 1
0 hours after culture	 <p>Figure 9 - Re-suspended OA chondrocytes (control without TGF-β1) immediately after being placed into the petri dish, (Scale bar = 100).</p>	 <p>Figure 10 - Re-suspended OA chondrocytes treated and cultured with TGF-β1 immediately after being placed into the petri dish, (Scale bar = 100).</p>

Analysis of glycosaminoglycan content using the SpectraMax M2/M2^e plate reader.

Figure 13 represent the glycosaminoglycan analysis and concentration curve for mean absorbance of DMMB dye in correlation to the concentration of exiting proteins via spectrophotometry analysis using the SoftPro max plate reader. This include “HCH – C” (healthy chondrocytes control), “HCH + TGF β 1” (healthy chondrocytes + TGF β 1), “OACH – C” (osteoarthritic chondrocyte control) and “OACH + TGF β 1” (osteoarthritic chondrocyte + TGF β 1).

A Concentration curve to show the mean absorbance of DMMB dye in correlation to the concentration of protein present.

Figure 13 - Displays a protein concentration curve obtained from the values provided via spectrophotometry analysis using the SoftPro max plate reader. Legends include “HCH – C” (healthy chondrocytes control), “HCH + TGF β 1” (healthy chondrocytes + TGF β 1), “OACH – C” (osteoarthritic chondrocyte control) and “OACH + TGF β 1” (osteoarthritic chondrocyte + TGF β 1).

Samples treated with TGF- β 1 with more staining of GAGs with DMMB, shows that TGF- β 1 does most definitely retain water, and hence is a large factor to be considered for curing OA. Samples without treatment of TGF- β 1 showed less absorbance as a result of reduction in glycosaminoglycan synthesis. The concentration curves for GAG’s in the output curve produced demonstrated higher absorbance in the samples containing TGF- β 1 than the samples without TGF- β 1 (See Figure 13). The osteoarthritic cells absorbed more light in plate reader compared with healthy chondrocytes, confirming that glycosaminoglycans are lost and less water is retained when osteoarthritis occurs. Also, absorbance values provided from the plate reader conveyed an increase in glycosaminoglycan staining in both the healthy and osteoarthritic samples induced with TGF- β 1 compared to their control groups, suggesting that the growth factor caused a slight form of upregulation in synthesis. Both variables when induced with 10ng/ml of TGF β 1 increased absorption of DMMB; TGF- β 1 induced water retention in both healthy and osteoarthritic cells. 2 Sample T tests were carried out for all collected results.

The P- value was less than 0.05 for two proteins concentration; when the protein concentration was 32%, the P- value was 0.004 and when the protein concentration was 21%, the P- value was 0.011. According to those values, one could assume GAG synthesis in healthy cells is significantly increased when compared to osteoarthritic cells and accept the alternative hypothesis.

5. Conclusion

The Culture of primary cells in the first 24 hours was successful, allowing acceptable doubling for a good quantity of cells to work with. The second culture of both the healthy and degraded cells was also a success, providing us with microscopic images, which portrayed images of rounded morphology in healthy cartilage cells in vitro, alongside a visual aid of the more fibroblastic differentiated morphology of osteoarthritic cells in vitro. Cells treated with and without TGF- β 1 were also successful, representing that the samples induced with TGF- β 1 (both healthy and osteoarthritic) contained a larger amount of Glycosaminoglycans. After treatment with TGF- β 1, rounded chondrocyte changed mainly to more fibroblastic morphology. The control samples did not show a dramatic change in terms of morphology. In conclusion, TGF- β 1 represent significant water retention for cartilage repair.
